

Chapter - 15

Simple Pointers

Things and Pointers to Things

There are things and pointers to things

A Small Town

Service (Variable Name)	Address (Address value)	Building (Thing)
Fire Department	1 Main Street	City Hall
Police Station	1 Main Street	City Hall
Planning office	1 Main Street	City Hall
Gas Station	2 Main Street	Ed's Gas Station

Pointer Operators

A pointer is declared by putting an asterisk (*) in front of the variable name in the declaration statement:

```
int thing;           // define "thing"
int *thing_ptr;      // define "pointer to a thing"
```

Pointer operations:

Operator	Meaning
*	<i>Dereference</i> (given a pointer, get the thing referenced)
&	<i>Address of</i> (given a thing, point to it)

Things and pointers to things

```
Thing  
thing = 4;  
&thing
```

A thing.

A pointer to thing. thing is an object. The & (address of) operator gets the address of an object (a pointers), so &thing is a pointer.

Example:

```
thing_ptr = &thing; // Point to the thing  
*thing_ptr = 5;      // Set "thing" to 5
```

```
thing_ptr
```

Thing pointer.

```
*thing_ptr
```

A thing.

```
thing_ptr = 5;      // Assign 5 to an integer
```

```
er
```

```
// We may or may not be
```

```
// pointing to the specific  
// integer "thing"
```

Make "thing_ptr" point to "thing"

```
thing_ptr = &thing;
```

Copy data from thing pointed to by 'thing_ptr' into 'other'

Setting the item pointed to by "thing_ptr" to the value 6.

```
*thing_ptr = 6;
```

How not to use pointer operators

`*thing`

Illegal. Asks C++ to get the object pointed to by the variable `thing`. Since `thing` is not a pointer, this is an invalid operation.

`&thing_ptr`

Legal, but strange. `thing_ptr` is a pointer. The `&` (address of) operator gets a pointer to the object (in this case `thing_ptr`). Result is pointer to a pointer. (Pointers to pointers do occur in more complex programs.)

Pointer Usage

```
#include <iostream>
main()
{
    int    thing_var;    // define a variable
    int    *thing_ptr;   // define a pointer

    thing_var = 2;        // assigning a value to thing
    std::cout << "Thing " << thing_var << '\n';

    thing_ptr = &thing_var; // make the pointer point to thing
    *thing_ptr = 3;         // thing_ptr points to thing_var so
                           // thing_var changes to 3
    std::cout << "Thing " << thing_var << '\n';

    // another way of printing the data
    std::cout << "Thing " << *thing_ptr << '\n';
    return (0);
}
```

Two pointers, one thing

```
1:      int      something;
2:
3:      int      *first_ptr;  // one pointer
4:      int      *second_ptr; // another pointer
5:
6:      something = 1;        // give the thing a value
7:
8:      first_ptr = &something;
9:      second_ptr = first_ptr;
```

Null Pointer

The null pointer points to nothing.

```
thing_ptr = NULL;
```

const Pointers

There are several flavors of constant pointers. It's important to know what the *const* applies to.

```
const char* first_ptr = "Forty-Two";  
first_ptr = "Fifty six";           // Legal or  
Illegal                             // Legal or  
*first_ptr = 'X';                  // Legal or  
Illegal
```

```
char* const second_ptr = "Forty-Two";  
second_ptr = "Fifty six";          // Legal or  
Illegal                             // Legal or  
*second_ptr = 'X';                 // Legal or  
Illegal
```

```
const char* const third_ptr = "Forty-Two";  
third_ptr = "Fifty six";           // Legal or  
Illegal                             // Legal or  
*third_ptr = 'X';                  // Legal or  
Illegal
```

Pointers and Printing

Example:

```
int an_integer = 5;           // A simple integer
int *int_ptr = &an_integer;  // Ptr to an integer

std::cout << "Integer pointer " << int_ptr << '\n';
```

outputs:

```
Integer pointer 0x58239A
```

Example:

```
// A Simple set of characters
char some_characters[10] = "Hello";
// Pointer to a character
char *char_ptr = &some_characters[0];

std::cout << "String pointer " << char_ptr << '\n';
```

outputs

```
String pointer Hello
```

Example

```
#include <iostream>
#include <iomanip.h>

const int ARRAY_SIZE = 10; // Number of characters in array
// Array to print
char array[ARRAY_SIZE] = "012345678";

int main()
{
    int index; /* Index into the array */

    for (index = 0; index < ARRAY_SIZE; ++index) {
        std::cout << hex;      // Trick to print hex numbers
        std::cout <<
            "&array[index]=0x" << int(&array[index]) <<
            " (array+index)=0x" << int(array+index) <<
            " array[index]=0x" << int(array[index]) << '\n',
        std::cout << dec;
    }
    return (0);
}
```

Output

```
&array[index]=0x20090 (array+index)=0x20090 array[index]=0x30
&array[index]=0x20091 (array+index)=0x20091 array[index]=0x31
&array[index]=0x20092 (array+index)=0x20092 array[index]=0x32
&array[index]=0x20093 (array+index)=0x20093 array[index]=0x33
&array[index]=0x20094 (array+index)=0x20094 array[index]=0x34
&array[index]=0x20095 (array+index)=0x20095 array[index]=0x35
&array[index]=0x20096 (array+index)=0x20096 array[index]=0x36
&array[index]=0x20097 (array+index)=0x20097 array[index]=0x37
&array[index]=0x20098 (array+index)=0x20098 array[index]=0x38
&array[index]=0x20099 (array+index)=0x20099 array[index]=0x0
```

Array Shorthand

```
array_ptr = &array[0];
```

is the same as:

```
array_ptr = array;
```

Summing an Array (Index Version)

```
#include <iostream>

int array[10] = {4, 5, 8, 9, 8, 1, 0, 1, 9, 3};
int index;

int main()
{
    index = 0;
    while (array[index] != 0)
        ++index;

    std::cout << "Number of elements before zero "
               << index << '\n';
    return (0);
}
```

Same Program Using Pointers

```
#include <iostream>

int array[10] = {4, 5, 8, 9, 8, 1, 0, 1, 9, 3};
int *array_ptr;

main()
{
    array_ptr = array;

    while ((*array_ptr) != 0)
        ++array_ptr;

    std::cout << "Number of elements before zero " <<
        (array_ptr - array) << '\n';
    return (0);
}
```

Zeroing an array

```
const int MAX = 10;

void init_array_1(int data[])
{
    int index;

    for (index = 0; index < MAX; ++index)
        data[index] = 0;
}

void init_array_2(int *data_ptr)
{
    int index;

    for (index = 0; index < MAX; ++index)
        *(data_ptr + index) = 0;
}

int main()
{
    int array[MAX];

    // one way of initializing the array
    init_array_1(array);

    // another way of initializing the array
    init_array_1(&array[0]);

    // Similar to the first method but
    // function is different
    init_array_2(array);

    return (0);
}
```

Splitting a C style string

Splitting a string

```
#include <iostream>
#include <string.h>
#include <stdlib.h>
main() {
    char line[80];    // The input line
    char *first_ptr;  // ptr we set to point to the first name
    char *last_ptr;   // ptr we set to point to the last name

    std::cin.getline(line, sizeof(line));

    last_ptr = line;    // last name is at beginning of line
    first_ptr = strchr(line, '/');    // Find slash

    // Check for an error
    if (first_ptr == NULL) {
        cerr << "Error: Unable to find slash in " << line <<
            '\n';
        exit (8);
    }

    *first_ptr = '\0';    // Zero out the slash
    ++first_ptr;          // Move to first character of name

    std::cout << "First:" << first_ptr << " Last:" << last_ptr << '\n';
    return (0);
}

char *strchr(char * string_ptr, char find) {
    while (*string_ptr != find) {
        // Check for end
        if (*string_ptr == '\0')
            return (NULL);    // not found
        ++string_ptr;
    }
    return (string_ptr);    // Found
}
```

Question: Why does this program print garbage?

```
#include <iostream>
#include <string.h>

/*****
 * tmp_name -- return a temporary file name
 *
 * Each time this function is called, a new name will
 * be returned.
 *
 * Returns
 *     Pointer to the new file name.
 *****/
char *tmp_name(void)
{
    char name[30];           // The name we are generating
    static int sequence = 0; // Sequence number for last digit

    ++sequence; // Move to the next file name

    strcpy(name, "tmp");

    // Put in the sequence digit
    name[3] = sequence + '0';

    // End the string
    name[4] = '\0';

    return(name);
}

int main()
{
    std::cout << "Name: " << tmp_name() << '\n';
    return(0);
}
```

Pointers and Structures

```
struct mailing {
    char name[60];      // last name, first name
    char address1[60]; // Two lines of street address
    char address2[60];
    char city[40];
    char state[2];      // Two character abbreviation
    long int zip;       // numeric zip code
} list[MAX_ENTRIES];

// Pointer to the data
struct mailing *list_ptrs[MAX_ENTRIES];

int current;    // current mailing list entry

// ....

for (current = 0; current = number_of_entries; ++current)
    list_ptrs = &list[current];

// Sort list_ptrs by zip code
```

Command Line Arguments

```
int main(int argc, char *argv[])  
{
```

<code>argc</code>	The number of arguments (program counts as one, so this number is
<code>always >= 1</code>).	
<code>argv</code>	The arguments (program name is <code>argv[0]</code>).

Example:

```
args this is a test
```

turns into:

<code>argc</code>	<code>= 5</code>
<code>argv[0]</code>	<code>= "args"</code>
<code>argv[1]</code>	<code>= "this"</code>
<code>argv[2]</code>	<code>= "is"</code>
<code>argv[3]</code>	<code>= "a"</code>
<code>argv[4]</code>	<code>= "test"</code>

Example

Our mission is to make the following program:

```
print_file [-v] [-l<length>]  
           [-o<name>] [file1] [file2] ...
```

-v Verbose option. Turns on a lot of progress information messages.

-l<length>

Set the page size to *<length>* lines. (Default = 66).

-o<name>

Set the output file to *<name>*. (Default = print.out)

print_file

```
/*
 * print -- format files for printing
 */
#include <iostream>
#include <stdlib.h>

int verbose = 0;           // verbose mode (default = false)
char *out_file = "print.out"; // output file name
char *program_name;        // name of the program (for errors)
int line_max = 66;         // number of lines per page

/*
 * do_file -- dummy routine to handle a file
 *
 * Parameter
 *      name -- name of the file to print
 */
void do_file(char *name) {
    std::cout << "Verbose " << verbose <<
        " Lines " << line_max <<
        " Input " << name <<
        " Output " << out_file << '\n';
}
```

print_file (cont)

```

/*****
 * usage -- tell the user how to use this program and
 *
 *          exit
 *****/
void usage(void)
{
    cerr << "Usage is " << program_name <<
        " [options] [file-list]\n";
    cerr << "Options\n";
    cerr << "  -v          verbose\n";
    cerr << "  -l<number>  Number of lines\n";
    cerr << "  -o<name>    Set output file name\n";
    exit (8);
}

```

print_file (cont)

```
main(int argc, char *argv[])
{
    // save the program name for future use
    program_name = argv[0];

    /*
     * loop for each option.
     *   Stop if we run out of arguments
     *   or we get an argument without a dash.
     */
    while ((argc > 1) && (argv[1][0] == '-')) {
        /*
         * argv[1][1] is the actual option character.
         */
        switch (argv[1][1]) {
            /*
             * -v verbose
             */
            case 'v':
                verbose = 1;
                break;
```

print_file (cont)

```
/*
 * -o<name>  output file
 *      [0] is the dash
 *      [1] is the "o"
 *      [2] starts the name
 */
case 'o':
    out_file = &argv[1][2];
    break;
/*
 * -l<number> set max number of lines
 */
case 'l':
    line_max = atoi(&argv[1][2]);
    break;
default:
    cerr << "Bad option " << argv[1] << '\n';
    usage();
}
```

print_file (cont)

```
/*
 * move the argument list up one
 * move the count down one
 */
++argv;
--argc;
}

/*
 * At this point all the options have been processed.
 * Check to see if we have no files in the list
 * and if so, we need to list just standard in.
 */
if (argc == 1) {
    do_file("print.in");
} else {
    while (argc > 1) {
        do_file(argv[1]);
        ++argv;
        --argc;
    }
}
return (0);
}
```
