

Chapter 15:

Inheritance, Polymorphism, and Virtual Functions

Addison-Wesley is an imprint of

15.1

What Is Inheritance?

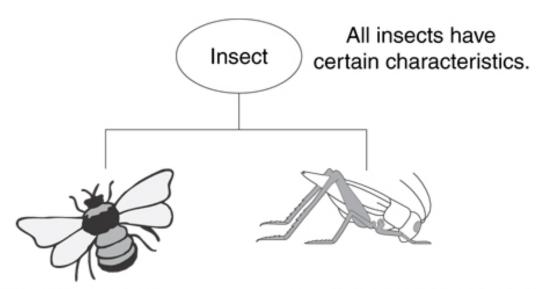

What Is Inheritance?

- Provides a way to create a new class from an existing class
- The new class is a specialized version of the existing class

Example: Insects

In addition to the common insect characteristics, the bumble bee has its own unique characteristics such as the ability to sting.

In addition to the common insect characteristics, the grasshopper has its own unique characteristics such as the ability to jump.

The "is a" Relationship

- Inheritance establishes an "is a" relationship between classes.
 - A poodle is a dog
 - A car is a vehicle
 - A flower is a plant
 - A football player is an athlete

Inheritance – Terminology and Notation

- Base class (or parent) inherited from
- Derived class (or child) inherits from the base class
- Notation:

Back to the 'is a' Relationship

- An object of a derived class 'is a(n)' object of the base class
- Example:
 - on UnderGrad is a Student
 - a Mammal is an Animal
- A derived object has all of the characteristics of the base class

What Does a Child Have?

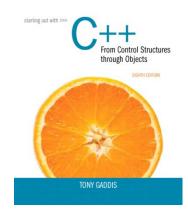

An object of the derived class has:

- all members defined in child class
- all members declared in parent class

An object of the derived class can use:

- all public members defined in child class
- all public members defined in parent class

15.2

Protected Members and Class Access

Protected Members and Class Access

protected member access specification: like private, but accessible by objects of derived class

Class access specification: determines how private, protected, and public members of base class are inherited by the derived class

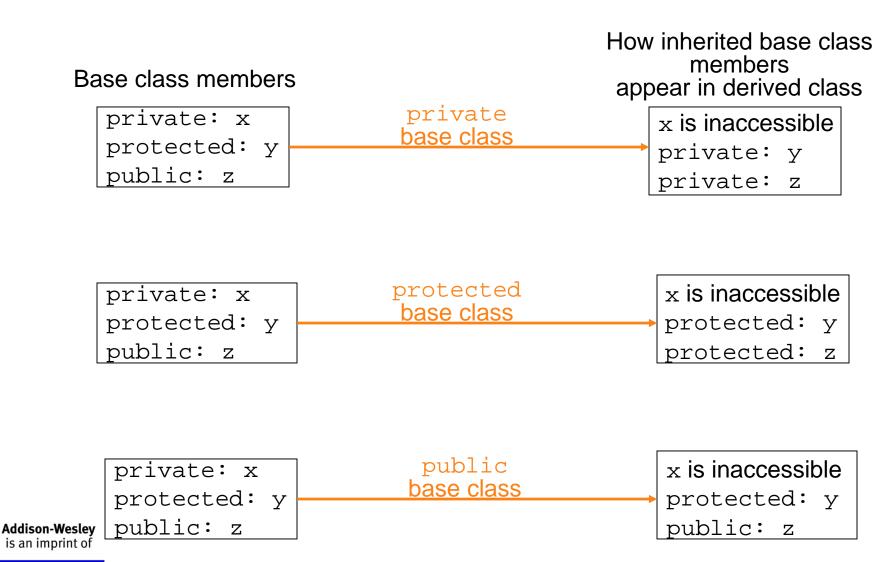

Class Access Specifiers

- 1) public object of derived class can be treated as object of base class (not viceversa)
- 2) protected more restrictive than public, but allows derived classes to know details of parents
- 3) private prevents objects of derived class from being treated as objects of base class.

Inheritance vs. Access

More Inheritance vs. Access

class Grade

```
private members:
   char letter;
   float score;
   void calcGrade();
public members:
   void setScore(float);
   float getScore();
   char getLetter();
```

When Test class inherits from Grade class using public class access, it looks like this:

```
class Test : public Grade

private members:
   int numQuestions;
   float pointsEach;
   int numMissed;

public members:
   Test(int, int);
```

```
private members:
   int numQuestions:
   float pointsEach;
   int numMissed;
public members:
   Test(int, int);
   void setScore(float);
   float getScore();
   float getLetter();
```

More Inheritance vs. Access (2)

class Grade

```
private members:
   char letter;
   float score;
   void calcGrade();
public members:
   void setScore(float);
   float getScore();
   char getLetter();
```

When Test class inherits from Grade class using protected class access, it looks like this:

```
class Test: protected Grade
private members:
   int numQuestions;
   float pointsEach;
   int numMissed;
public members:
   Test(int, int);
```

```
private members:
   int numQuestions:
   float pointsEach;
   int numMissed;
public members:
   Test(int, int);
protected members:
   void setScore(float);
   float getScore();
   float getLetter();
```

More Inheritance vs. Access (3)

class Grade

```
private members:
   char letter;
   float score;
   void calcGrade();
public members:
   void setScore(float);
   float getScore();
   char getLetter();
```

When Test class inherits from Grade class using private class access, it looks like this:

```
class Test : private Grade
private members:
   int numQuestions;
   float pointsEach;
   int numMissed;
public members:
   Test(int, int);
```

```
private members:
   int numQuestions:
   float pointsEach;
   int numMissed;
   void setScore(float);
   float getScore();
   float getLetter();
   public members:
    Test(int, int);
```

15.3

Constructors and Destructors in Base and Derived Classes

Constructors and Destructors in Base and Derived Classes

- Derived classes can have their own constructors and destructors
- When an object of a derived class is created, the base class's constructor is executed first, followed by the derived class's constructor
- When an object of a derived class is destroyed, its destructor is called first, then that of the base class

Constructors and Destructors in Base and Derived Classes

Program 15-4

Program 15-4 (continued)

```
10 class BaseClass
11
12
  public:
13
      BaseClass() // Constructor
         { cout << "This is the BaseClass constructor.\n"; }
14
1.5
16
      ~BaseClass() // Destructor
17
         { cout << "This is the BaseClass destructor.\n"; }
18
  };
19
   //**********
   // DerivedClass declaration
   //**********
22
23
   class DerivedClass : public BaseClass
24
25
   public:
26
27
      DerivedClass() // Constructor
28
         { cout << "This is the DerivedClass constructor.\n"; }
29
      ~DerivedClass() // Destructor
3.0
31
         { cout << "This is the DerivedClass destructor.\n"; }
32 };
33
```

Addison-Wesley is an imprint of

Program 5-14 (Continued)

```
//*********
35 // main function
36
   //********
37
38
   int main()
39
40
     cout << "We will now define a DerivedClass object.\n";
41
     DerivedClass object;
42
43
44
     cout << "The program is now going to end.\n";
45
     return 0;
46 }
```

Program Output

```
We will now define a DerivedClass object.
This is the BaseClass constructor.
This is the DerivedClass constructor.
The program is now going to end.
This is the DerivedClass destructor.
This is the BaseClass destructor.
```

Passing Arguments to Base Class Constructor

- Allows selection between multiple base class constructors
- Specify arguments to base constructor on derived constructor heading:

```
Square::Square(int side)
              Rectangle(side, side)
```

- Can also be done with inline constructors
- Must be done if base class has no default constructor

Passing Arguments to Base Class Constructor

derived class constructor

base class constructor

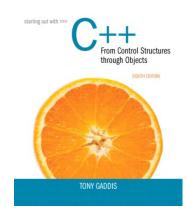

Square::Square(int side):Rectangle(side, side)

derived constructor parameter

base constructor parameters

15.4

Redefining Base Class Functions

Redefining Base Class Functions

Redefining function: function in a derived class that has the same name and parameter list as a function in the base class

Typically used to replace a function in base class with different actions in derived class

Redefining Base Class Functions

Not the same as overloading – with overloading, parameter lists must be different

Objects of base class use base class version of function; objects of derived class use derived class version of function

Base Class

```
class GradedActivity
protected:
  char letter; // To hold the letter grade
  double score; // To hold the numeric score
  void determineGrade(); // Determines the letter grade
public:
  // Default constructor
  GradedActivity()
      { letter = ' '; score = 0.0; }
   // Mutator function
  void setScore(double s) ← Note setScore function
      { score = s;
       determineGrade();}
   // Accessor functions
  double getScore() const
      { return score; }
  char getLetterGrade() const
     { return letter; }
};
```

Addison-Wesley is an imprint of

Derived Class

```
1 #ifndef CURVEDACTIVITY H
 2 #define CURVEDACTIVITY H
  #include "GradedActivity.h"
  class CurvedActivity : public GradedActivity
 6
   protected:
      double rawScore; // Unadjusted score
 8
      double percentage; // Curve percentage
   public:
      // Default constructor
11
12
      CurvedActivity() : GradedActivity()
         { rawScore = 0.0; percentage = 0.0; }
13
14
15
      // Mutator functions
      void setScore(double s) ← Redefined setScore function
16
17
         { rawScore = s;
           GradedActivity::setScore(rawScore * percentage); }
18
19
      void setPercentage(double c)
20
21
         { percentage = c; }
22
23
      // Accessor functions
24
      double getPercentage() const
25
         { return percentage; }
26
27
      double getRawScore() const
         { return rawScore; }
28
   };
3.0
   #endif
```

Addison-Wesley is an imprint of

From Program 15-7

```
13
       // Define a CurvedActivity object.
14
       CurvedActivity exam;
15
16
      // Get the unadjusted score.
17
      cout << "Enter the student's raw numeric score: ";
18
      cin >> numericScore;
19
20
       // Get the curve percentage.
      cout << "Enter the curve percentage for this student: ";
21
22
       cin >> percentage;
23
24
       // Send the values to the exam object.
25
       exam.setPercentage(percentage);
26
       exam.setScore(numericScore);
27
28
      // Display the grade data.
29
      cout << fixed << setprecision(2);
3.0
      cout << "The raw score is "
3.1
            << exam.getRawScore() << endl;
32
      cout << "The curved score is "
3.3
            << exam.getScore() << endl;
34
       cout << "The curved grade is "
35
            << exam.qetLetterGrade() << endl;
```

Program Output with Example Input Shown in Bold

```
Enter the student's raw numeric score: 87 [Enter]
Enter the curve percentage for this student: 1.06 [Enter]
The raw score is 87.00
The curved score is 92.22
The curved grade is A
```

Problem with Redefining

- Consider this situation:
 - Class BaseClass defines functions x() and y(). x() calls y().
 - Class DerivedClass inherits from BaseClass and redefines function y().
 - An object D of class DerivedClass is created and function x() is called.
 - When x() is called, which y() is used, the one defined in BaseClass or the the redefined one in DerivedClass?

Problem with Redefining

BaseClass

```
void X();
void Y();
```

DerivedClass

```
void Y();
```

```
DerivedClass D;
D.X();
```

Object D invokes function X() in BaseClass Function X() invokes function Y() in BaseClass and not function Y() in DerivedClass

Function calls are bound at compile time. This is static binding.

15.5

Class Hierarchies

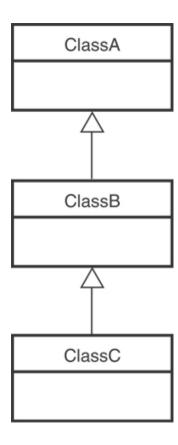

Class Hierarchies

A base class can be derived from another

base class.

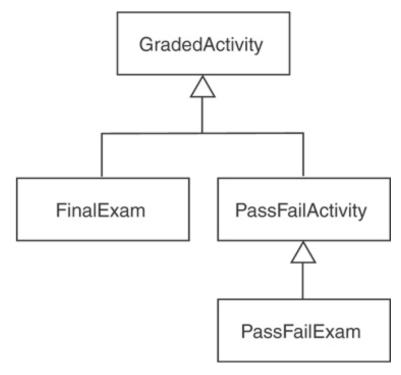

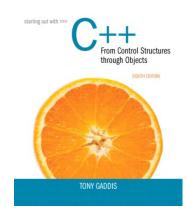

Class Hierarchies

Consider the GradedActivity, FinalExam, PassFailActivity, PassFailExam hierarchy in Chapter 15.

15.6

Polymorphism and Virtual Member Functions

Polymorphism and Virtual Member Functions

- Virtual member function: function in base class that expects to be redefined in derived class
- Function defined with key word virtual:
 virtual void Y() {...}
- Supports dynamic binding: functions bound at run time to function that they call
- Without virtual member functions, C++ uses static (compile time) binding

Consider this function (from Program 15-9)

Because the parameter in the displayGrade function is a GradedActivity reference variable, it can reference any object that is derived from GradedActivity.

A problem occurs in Program 15-10 however...

Addison-Wesley

Program 15-10

```
#include <iostream>
 2 #include <iomanip>
 3 #include "PassFailActivity.h"
    using namespace std;
 5
   // Function prototype
    void displayGrade(const GradedActivity &);
8
 9
    int main()
10
11
       // Create a PassFailActivity object. Minimum passing
12
       // score is 70.
13
       PassFailActivity test(70);
14
15
       // Set the score to 72.
16
       test.setScore(72);
17
18
       // Display the object's grade data. The letter grade
19
       // should be 'P'. What will be displayed?
20
       displayGrade(test);
       return 0;
21
22 }
```

```
23
 24
    //*********************
 25
    // The displayGrade function displays a GradedActivity object's *
    // numeric score and letter grade.
26
 27
    //*********************
28
29
    void displayGrade(const GradedActivity &activity)
 3.0
31
       cout << setprecision(1) << fixed;</pre>
32
       cout << "The activity's numeric score is "
33
           << activity.getScore() << endl;
       cout << "The activity's letter grade is "
34
35
           << activity.getLetterGrade() << endl;</pre>
36
Program Output
The activity's numeric score is 72.0
The activity's letter grade is C
```

The getLetterGrade member function returned 'C' instead of 'P'.

GradedActivity class's getLetterGrade function was executed instead of the PassFailActivity class's version of the function.

Static Binding

Program 15-10 displays 'C' instead of 'P' because the call to the getLetterGrade function is statically bound (at compile time) with the GradedActivity class's version of the function.

• We can remedy this by making the function virtual.

Virtual Functions

A virtual function is dynamically bound to calls at runtime.

At runtime, C++ determines the type of object making the call, and binds the function to the appropriate version of the function.

Virtual Functions

To make a function virtual, place the virtual key word before the return type in the base class's declaration:

```
virtual char getLetterGrade() const;
```

The compiler will not bind the function to calls. Instead, the program will bind them at runtime.

Updated Version of GradedActivity

```
class GradedActivity
    protected:
 8
 9
       double score; // To hold the numeric score
10
    public:
11
       // Default constructor
12
       GradedActivity()
          { score = 0.0; }
1.3
14
15
       // Constructor
       GradedActivity(double s)
16
17
          { score = s; }
1.8
       // Mutator function
19
20
       void setScore(double s)
          { score = s; }
21
                                        The function
22
                                        is now virtual
23
       // Accessor functions
       double getScore() const
24
25
          { return score; }
26
27
       virtual char getLetterGrade() const;
28
```

The function also becomes virtual in all derived classes automatically!

If we recompile our program with the updated versions of the classes, we will get the right output, shown here: (See Program 15-11 in the book.)

Program Output

```
The activity's numeric score is 72.0
The activity's letter grade is P
```

This type of behavior is known as polymorphism. The term *polymorphism* means the ability to take many forms.

Program 15-12 demonstrates polymorphism by passing objects of the GradedActivity and PassFailExam classes to the displayGrade function.

Program 15-12

```
#include <iostream>
 2 #include <iomanip>
   #include "PassFailExam.h"
    using namespace std;
 4
 5
 6
    // Function prototype
    void displayGrade(const GradedActivity &);
 8
 9
    int main()
10
11
       // Create a GradedActivity object. The score is 88.
12
       GradedActivity test1(88.0);
13
14
       // Create a PassFailExam object. There are 100 questions,
15
       // the student missed 25 of them, and the minimum passing
16
       // score is 70.
17
       PassFailExam test2(100, 25, 70.0);
18
19
       // Display the grade data for both objects.
20
       cout << "Test 1:\n";</pre>
21
       displayGrade(test1); // GradedActivity object
       cout << "\nTest 2:\n";</pre>
22
```

```
23
       displayGrade(test2); // PassFailExam object
       return 0;
 24
 25
 26
 27
    //*********************
 28
    // The displayGrade function displays a GradedActivity object's *
 29
    // numeric score and letter grade.
    //********************
 3.0
 31
 32
    void displayGrade(const GradedActivity &activity)
 33
 34
       cout << setprecision(1) << fixed;</pre>
 35
       cout << "The activity's numeric score is "
 36
            << activity.getScore() << endl;
 37
       cout << "The activity's letter grade is "
            << activity.getLetterGrade() << endl;</pre>
 38
 39
Program Output
Test 1:
The activity's numeric score is 88.0
The activity's letter grade is B
Test 2:
The activity's numeric score is 75.0
The activity's letter grade is P
```

Addison-Wesley is an imprint of

Polymorphism Requires References or Pointers

Polymorphic behavior is only possible when an object is referenced by a reference variable or a pointer, as demonstrated in the displayGrade function.

Base Class Pointers

- Can define a pointer to a base class object
- Can assign it the address of a derived class object

```
GradedActivity *exam = new PassFailExam(100, 25, 70.0);
cout << exam->getScore() << endl;
cout << exam->getLetterGrade() << endl;</pre>
```

Base Class Pointers

- Base class pointers and references only know about members of the base class
 - So, you can't use a base class pointer to call a derived class function
- Redefined functions in derived class will be ignored unless base class declares the function virtual

Redefining vs. Overriding

In C++, redefined functions are statically bound and overridden functions are dynamically bound.

So, a virtual function is overridden, and a non-virtual function is redefined.

Virtual Destructors

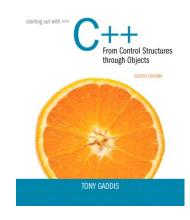

- It's a good idea to make destructors virtual if the class could ever become a base class.
- Otherwise, the compiler will perform static binding on the destructor if the class ever is derived from.
- See Program 15-14 for an example

C++ 11's override and final Key Words

- The override key word tells the compiler that the function is supposed to override a function in the base class.
- When a member function is declared with the final key word, it cannot be overridden in a derived class.
- See Programs 15-7 and 15-8 for an example

15.7

Abstract Base Classes and Pure Virtual Functions

Abstract Base Classes and Pure Virtual Functions

- Pure virtual function: a virtual member function that <u>must</u> be overridden in a derived class that has objects
- Abstract base class contains at least one pure virtual function:

```
virtual void Y() = 0;
```

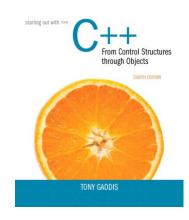

- The = 0 indicates a pure virtual function
- Must have no function definition in the base class

Abstract Base Classes and Pure Virtual Functions

- Abstract base class: class that can have no objects. Serves as a basis for derived classes that may/will have objects
- A class becomes an abstract base class when one or more of its member functions is a pure virtual function

15.8

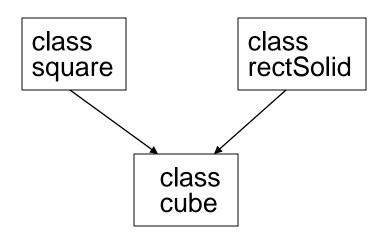

Multiple Inheritance

Multiple Inheritance

- A derived class can have more than one base class
- Each base class can have its own access specification in derived class's definition:

Multiple Inheritance

Arguments can be passed to both base classes' constructors:

```
cube::cube(int side) :
square(side),
rectSolid(side, side, side);
```

Base class constructors are called in order given in class declaration, not in order used in class constructor

Multiple Inheritance

- Problem: what if base classes have member variables/functions with the same name?
- Solutions:
 - Derived class redefines the multiply-defined function
 - Derived class invokes member function in a particular base class using scope resolution operator : :
- Compiler errors occur if derived class uses base class function without one of these solutions
